

NodeJS - exercise 1

Create a NodeJS project to manage a DB of users:

- Create a User interface with name, ID, and year of birth.
- Create a service class, add an empty array of users in the c'tor.
- Add the following functions to the service class:
 - o Add user – should validate the ID (Israeli ID number) and the year of birth, and add the user to the array.
 - o Get the oldest user.
 - o Get all the names of the users, in alphabetical order, with no duplicates.

For the last two functions, use the **lodash** npm package.

- Add a main function to test your code
Bonus: add unit tests instead.
- Add a script to the package.json file that runs the main code.

Notes:

- All code should be written in Typescript, including types for all objects, functions, input, and return types.
- The code should follow all TypeScript and NodeJS conventions.
- The main file or unit tests should test all functions.
